---

## Respiration: Physiological and Cellular

---

---

---

---

---

---

---

---

## Breathing (Gas Exchange)

- Two primary operating features of gas exchange
  - The **respiratory medium**, either air or water
  - The **respiratory surface**, a wetted epithelium over which gas exchange takes place
- In some invertebrates, the **skin** is the respiratory surface
- In other invertebrates and all vertebrates, **gills** or **lungs** are the primary respiratory surfaces

---

---

---

---

---

---

---

---

## Respiratory Surface Area

a. Extended body surface: flatworm

b. External gills: mudpuppy

c. Lungs: human

---

---

---

## Gas Exchange

- Simple diffusion of molecules drives exchange of gases across the respiratory surface
- **Area of respiratory surface** determines total quantity of gases exchanged by diffusion
- **Respiratory surfaces must be thin, why?**
- Concentration gradients of  $O_2$  and  $CO_2$  across respiratory surfaces are kept at optimal levels by **ventilation** and **perfusion**

---

---

---

---

---

---

---

---

## Water Breathers

- Respiratory surfaces are wetted by direct exposure to the environment
- Require significant energy to keep respiratory surfaces ventilated
  - High density and viscosity of water
  - Relatively low  $O_2$  content compared with air

---

---

---

---

---

---

---

---

## External and Internal Gills

A. External gills: nudibranch

B. Internal gills: clam

C. Internal gills: cuttlefish

D. Internal gills: fish

## Countercurrent Exchange

- In sharks, bony fishes, and some crabs
  - Water moves in a one-way direction over the gills, against (or opposite) the flow of blood
  - Maximizes exchange of gases over the respiratory surface

A. The flow of water around the gill filaments

B. Countercurrent flow in fish gills, in which the blood and water move in opposite directions

**C.** In countercurrent exchange, blood leaving the capillaries has the same  $O_2$  content as fully oxygenated water entering the gills

## Air Breathers

- Air is high in  $O_2$  content
  - Allows air-breathers to maintain higher metabolic levels than water breathers
- Air has lower density and viscosity than water
  - Allows air breathers to ventilate respiratory surfaces with relatively little energy
- **What is the disadvantage of breathing air?**

## Insects: Tracheal System

## Lungs (Air Breathers)

- Invaginations of the body surface
  - Allow air to become saturated with water before it reaches the respiratory surface
- Lung ventilation
  - **Positive pressure breathing** (frogs)
  - **Negative pressure breathing** (reptiles and mammals)
  - Birds have the most complex and efficient system (read about this in the text)

## Respiratory Movements

---

---

---

---

---

---

---

---

## Measuring Lung Ventilation

- **Tidal volume**
  - Amount of air moved in and out of lungs during an inhalation and exhalation
- **Vital capacity**
  - Total volume of air a person can inhale and exhale by breathing as deeply as possible
- **Residual volume**
  - Air remaining in the lungs after as much air as possible is exhaled

## O<sub>2</sub> Transport

- O<sub>2</sub> diffuses from alveolar air into blood
  - **Partial pressure** of oxygen is higher in the alveolar air than in the blood capillaries at the lungs
- Most O<sub>2</sub> entering the blood combines with **hemoglobin** inside erythrocytes
- The respiratory pigment of almost all vertebrates is the protein **hemoglobin**
- Like all respiratory pigments, hemoglobin must reversibly bind O<sub>2</sub>, **loading O<sub>2</sub> in the lungs** and **unloading it in other parts of the body**

## Hemoglobin

Hemoglobin consists of four subunits, each with a cofactor called a **heme group** that has an iron atom at its center

## O<sub>2</sub> Diffuses into Body Cells

- O<sub>2</sub> concentration (**partial pressure of oxygen**) in interstitial fluid and body cells is lower than in blood plasma
- **O<sub>2</sub> diffuses from blood** into interstitial fluid, and from interstitial fluid **into body cells**
- **Effect of pH** on oxygen release from hemoglobin
  - **Bohr shift (effect)**: O<sub>2</sub> released from hemoglobin at lower pH (higher CO<sub>2</sub> concentration)
  - **Carbonic acid (H<sub>2</sub>CO<sub>3</sub>)**

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

## CO<sub>2</sub> Transfer: Body Tissues

- **Partial pressure of CO<sub>2</sub>** is higher in tissues than in blood
  - About 10% of CO<sub>2</sub> dissolves in blood plasma
  - **70% is converted into H<sup>+</sup> and HCO<sub>3</sub><sup>-</sup> (bicarbonate) ions**
  - 20% combines with hemoglobin

---

---

---

---

---

---

---

---

## CO<sub>2</sub> Transfer: Body Tissues

## CO<sub>2</sub> Transfer: Lungs

- In the lungs, **partial pressure of CO<sub>2</sub>** is higher in blood than in alveolar air
  - Reactions packing CO<sub>2</sub> into blood are reversed
  - CO<sub>2</sub> is released from blood into alveolar air

## CO<sub>2</sub> Transfer: Lungs
